CIS 371 Web Application Programming

TypeScript IV

Lecturer: Dr. Yong Zhuang

Based on the original version by Professor Hans Dulimarta.

Recall

- TypeScript Functions (& Lambdas):
  - Named, Anonymous, Lambda(Fat Arrow) Function
  - Single-line return contraction
- High-Order Function and callback function (Functions as Arguments)
  - Array.sort()
  - Array.reduce()

Practice

Answer

Reduce: Array of objects

```
type River = {
  name: string;
  countries: Array<string>; // the river passes thru these countries
  lenInMiles: number; // river length in miles
};
```

```
const waters: Array<River> = [
  {
    name: "Amazon",
    countries: ["Brazil", "Columbia", "Peru"],
    lenInMiles: 4132,
  },
  { name: "Nile", countries: ["Egypt"], lenInMiles: 4388 },
  { name: "Mississippi", countries: ["US"], lenInMiles: 2340 },
  {
    name: "Mekong",
    countries: ["China", "Myanmar", "Laos", "Thailand", "Vietnam"],
    lenInMiles: 2703,
  },
  { name: "Ganges", countries: ["India", "Bangladesh"], lenInMiles: 1560 },
];
```

The name of the longest river?

```
type River = {
  name: string;
  countries: Array<string>;
  lenInMiles: number;
};
```

Practice

The name of the longest river?

```
type River = {
  name: string;
  countries: Array<string>;
  lenInMiles: number;
};
```

```
function lengthCompare(prev: River, curr: River): River {
  if (prev.lenInMiles > curr.lenInMiles) return prev;
  else return curr;
}
let winner: River;
winner = waters.reduce(lengthCompare);
console.log(winner.name);
```

Practice

```
let winner: River;
winner = waters.reduce((prev: River, curr: River): River => {
  if (prev.lenInMiles > curr.lenInMiles) return prev;
  else return curr;
});
console.log(winner.name);
```

What is the length of the longest river (in miles)?

```
type River = {
  name: string;
  countries: Array<string>;
  lenInMiles: number;
};
```

Practice

What is the length of the longest river (in miles)?

```
type River = {
  name: string;
  countries: Array<string>;
  lenInMiles: number;
};
```

```
function compLength(prev: River, curr: River): River {
  if (prev.lenInMiles > curr.lenInMiles) return prev;
  else return curr;
}
let winner: River;
winner = waters.reduce(compLength);
console.log("Longest mile is", winner.lenInMiles);
```

Practice

```
function compRivLen(prev: number, curr: River): number {
  if (prev > curr.lenInMiles) return prev;
  else return curr.lenInMiles;
}
let winner: number;
winner = waters.reduce(compRivLen, Number.MIN_VALUE);
console.log("Longest mile is", winner);
```

Which river flows through the most countries?

```
type River = {
  name: string;
  countries: Array<string>;
  lenInMiles: number;
};
```

Practice

Which river flows through the most countries?

```
type River = {
  name: string;
  countries: Array<string>;
  lenInMiles: number;
};
```

```
function countryCompare(prev: River, curr: River): River {
  if (prev.countries.length > curr.countries.length) return prev;
  else return curr;
}
let winner: River;
winner = waters.reduce(countryCompare);
console.log(winner.name);
```

Practice

```
let winner: River;
winner = waters.reduce((prev: River, curr: River): River => {
  if (prev.countries.length > curr.countries.length) return prev;
  else return curr;
});
console.log(winner.name);
```

.reduce() vs .reduceRight()

Build a string of river names with reduce

```
const riverNames1 = waters.reduce((acc, river) => {
  return acc + " -> " + river.name;
}, "");

console.log(riverNames1);
```

.reduce()

Run the sample code here to Compare the outputs of .reduce() and .reduceRight()

What is the difference between reduce and reduceRight?

```
const riverNames2 = waters.reduceRight((acc, river) => {
  return acc + " -> " + river.name;
}, "");

console.log(riverNames2);
```

.reduceRight()

More Array high-order functions

- Array.every(), Array.some()
- Array.find(), findIndex()
- Array.filter(), Array.map(), Array.flatmap()
- Array.forEach()
- … and many others
- flatMap() is available in ES2019

```
// tsconfig.json {
  "compilerOptions": {
    "target": "ES2019",
    // other options go here
  }
  ...
}
```

Array high-order functions

```
type Shape = {
  color: string;
  numSides: number;
  sideDims: Array<number>; // the length of each side
};
```

```
let shapes: Array<Shape> = [_____]
```

Array.some(): do we have any green shape?

shapes.some (?????) → Yes

```
function isGreen(s: Shape): boolean {
    return s.color === "green"
}

const someGreen = shapes.some(isGreen);
console.log(someGreen);  // true
```

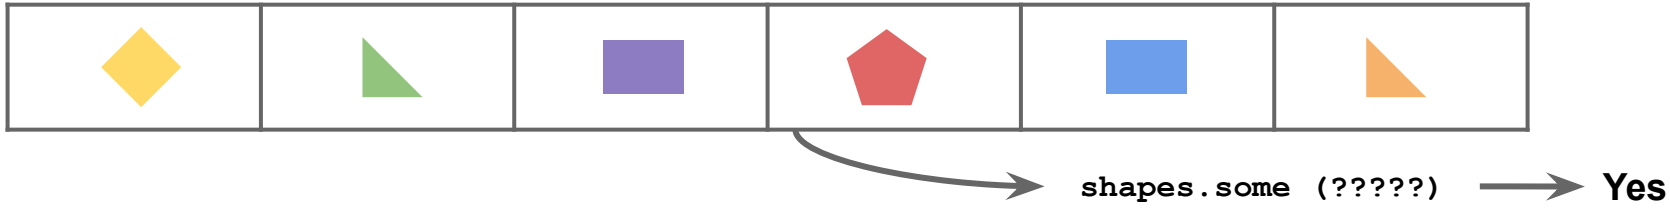
- *Purpose: Test if at least one element in the array passes the test implemented by the provided function.*
- *Return value: **A Boolean** (true if at least one passes the test, otherwise false).*

```
const someGreen = shapes.some(function (s: Shape): boolean {
  return s.color === "green";                    // Anonymous function
});

const someGreen = shapes.some((s: Shape): boolean => {
  return s.color === "green";                    // Anonymous fat arrow
});

const someGreen = shapes.some((s: Shape): boolean => s.color === "green");
                                                 // 1 line return elimination
const someGreen = shapes.some((s) => s.color === "green");
                                                 // No explicit type
```

Array.some(): do we have any green shape?



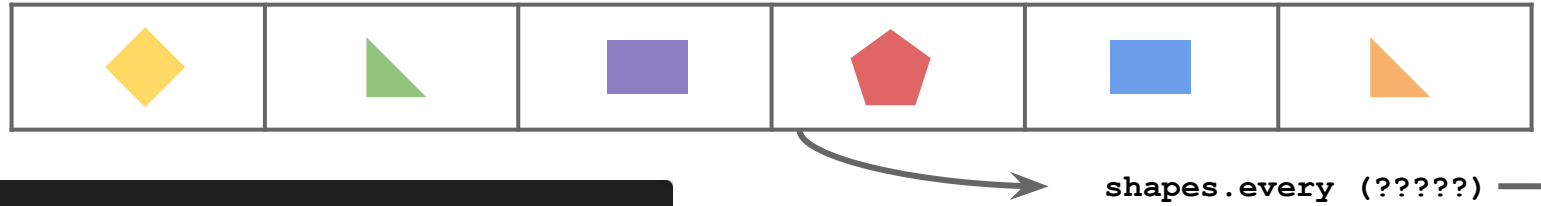
Incorrect!!!

```
function isGreen(col: string): boolean {
  return col === "green";
}

const someGreen = shapes.some(isGreen);
console.log(someGreen); // true
```

// isGreen must take a Shape as its input parameter
// NOT a string!!!

Array.every(): are all shapes triangle?



```
function isTriangle(s: Shape): boolean {
  return s.numSides === 3;
}

const allTriangle = shapes.every(isTriangle);
console.log(allTriangle); // false
```

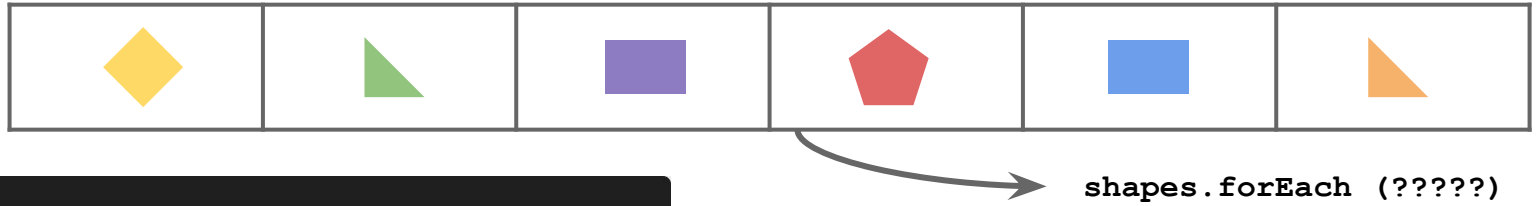
- *Purpose: Tests whether all elements in the array pass the test implemented by the provided function.*
- *Return value: **A Boolean** (true if every element passes the test, otherwise false).*

```
const allTriangle = shapes.every(function (s: Shape): boolean {
  return s.numSides === 3;                          // Anonymous function
});

const allTriangle = shapes.every((s: Shape): boolean => {
  return s.numSides === 3;                          // Anonymous fat arrow
});

const allTriangle = shapes.every((s: Shape): boolean => s.numSides === 3);
                                                    // 1 line return elimination
const allTriangle = shapes.every((s) => s.numSides === 3);
                                                    // No explicit type
```

Array.forEach(): inspect all shapes



```
function printShape(s: Shape): void {
  console.log("# of sides", s.numSides);
}

shapes.forEach(printShape);
```

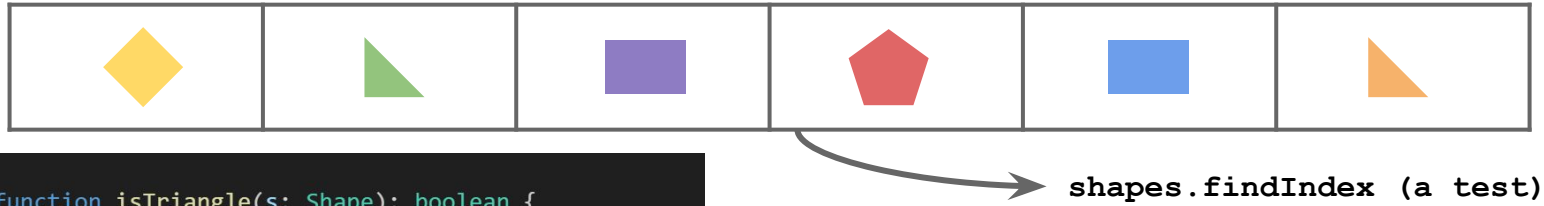
- *Purpose: Executes a provided function once for each array element.*
- *Return value:* ***undefined.***

```
shapes.forEach(function (s: Shape): void {
  console.log("# of sides", s.numSides);
});                    // Anonymous function

shapes.forEach((s: Shape): void => {
  console.log("# of sides", s.numSides);
});                    // Anonymous fat arrow

shapes.forEach((s) => {
  console.log("# of sides", s.numSides);
});                    // No explicit type
```

Array.findIndex(): where is ...?



```
function isTriangle(s: Shape): boolean {
  return s.numSides === 3;
}

const idxTriangle = shapes.findIndex(isTriangle);
console.log(idxTriangle); // 1
```

- *Purpose: To find the index of the **first element** in the array that satisfies a provided testing function.*
- *Return value: the index of the **first element** in the array that passes the test. If **no elements** pass the test, it returns **-1**.*

```
const idxTriangle = shapes.findIndex(function (s: Shape): boolean {
  return s.numSides === 3;
});

const idxTriangle = shapes.findIndex((s: Shape): boolean => {
  return s.numSides === 3;
});

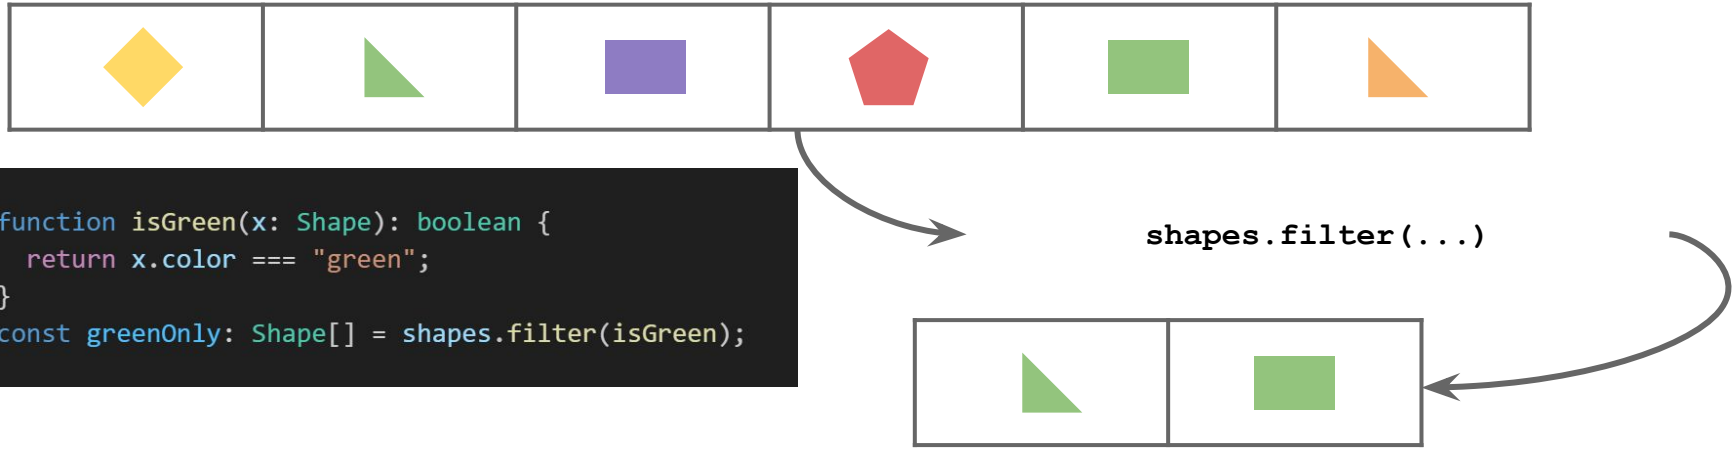
const idxTriangle = shapes.findIndex((s: Shape): boolean => s.numSides === 3);

const idxTriangle = shapes.findIndex((s) => s.numSides === 3);
```

Array .find() Family of Functions

- If you need the actual element that satisfies a condition in the array, use **find()**.
- If you need the index of the found element in the array that satisfies a condition, use **findIndex()**.
- If you need to find the index of a specific value in the array, use **indexOf()**. (It's similar to findIndex(), but checks each element for equality with the value instead of using a testing function.)
- If you need to determine whether an array includes a specific value, use **includes()**. Again, it checks each element for equality with the value instead of using a testing function.
- If you need to find if any element satisfies the provided testing function, use **some()**.

Array.filter(): give me only green shapes



```
function isGreen(x: Shape): boolean {
  return x.color === "green";
}
const greenOnly: Shape[] = shapes.filter(isGreen);
```

- *Purpose: creates a new array with all elements that pass the test implemented by the provided function.*
- *Return value: a new array with the elements that pass the test. If no elements pass the test, an empty array will be returned.*

```
const greenOnly = shapes.filter((shp: Shape): boolean => {
  return shp.color === "green";
});

const greenOnly = shapes.filter((x) => x.color === "green");
```

Array.map(): extract all colors/num sides

`shapes.map(--color--)`

array of strings

`["yellow", "green", "purple", "red", "green", "orange"]`

6-item array

`shapes.map(--numSides--)`

array of numbers

`[4, 3, 4, 5, 4, 3]`

```
let colors: string[];

colors = shapes.map((x: Shape) => {
  return x.color;
});

//or
colors = shapes.map((x) => x.color);
```

```
let sides: number[];

sides = shapes.map((x: Shape) => {
  return x.numSides;
});

//or
sides = shapes.map((x) => x.numSides);
```

Array.filter() & Array.map()

.filter()

```
// Named Function
const numbers = [2, -30, 0, 17, 9, -11];
function isPos(x: number): boolean {
  return x > 0;
}
const out = numbers.filter(isPos);
console.log(out); // [2, 17, 19]
```

```
// Fat arrow
const numbers = [2, -30, 0, 17, 9, -11];
const out = numbers.filter((x: number) => {
  return x > 0;
});
console.log(out); // [2, 17, 19]
```

To create a new array with elements that pass a condition (or test) from the original array.

.map()

```
const numbers = [2, -30, 0, 17, 9, -11];
function plus10(x: number): number {
  return x + 10;
}
const out = numbers.map(plus10);
console.log(out); // [12, -20, 10, 27, 19, -1]
```

```
const numbers = [2, -30, 0, 17, 9, -11];
const out = numbers.map((x: number) => {
  return x + 10;
});
console.log(out); // [12, -20, 10, 27, 19, -1]
```

To create a new array by transforming each element in the original array.

Chaining multiple Array functions

`map(--color--)`

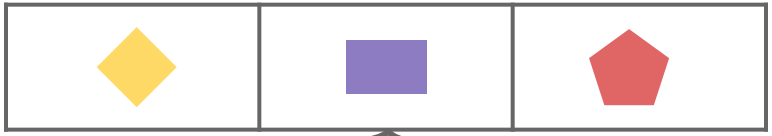
```
["yellow", "green", "purple", "red", "green", "orange"]
```

`filter(c === “green”)`

```
["green", "green"]
```

```
const someBlue = shapes.map((x) => x.color).filter((c) => c === "green");
```

Array.flatmap(): from one to many



`shapes.flatmap(--sideDims--)`

length = 13

```
[7, 7, 7, 7, 8, 11, 8, 11, 6.1, 6.1, 6.1, 6.1, 6.1]
```

`shapes.map(--sideDims--)`

length = 3

```
[
  [7, 7, 7, 7],
  [8, 11, 8, 11],
  [6.1, 6.1, 6.1, 6.1, 6.1],
]
```

```
let stats: number[];
stats = shapes.flatMap((s: Shape): number[] => {
  return s.sideDims;
});
stats = shapes.flatMap((s: Shape): number[] => s.sideDims);
```

```
let stats: number[][];
stats = shapes.map((s: Shape): number[] => {
  return s.sideDims;
});
stats = shapes.map((s: Shape): number[] => s.sideDims);
```

Practical Use Case of flatmap()

```
type Course = {
  name: string;
  credits: number;
  classList: Array<string>;
};
let allCourses: Array<Course> = [
  {
    name: "MTH101 Calculus",
    credits: 4,
    classList: [
      /* 25 student names */
    ],
  },
  {
    name: "HTM 203 Beer Brewing",
    credits: 2,
    classList: [
      /* 70 student names */
    ],
  },
];
```

Find all students whose name begins with "Eli"

```
const studentList = allCourses
  .flatMap((c: Course) => {
    return c.classList;
  })
  // you'll get 95 names from flatMap
  .filter((who: string) => {
    return who.startsWith("Eli");
  });
```

```
const studentList = allCourses
  .flatMap((c: Course) => c.classList)
  // you'll get 95 names from flatMap
  .filter((who: string) => who.startsWith("Eli"));
```

Some examples

How many green shapes?

```
shapes.filter((s) => s.color === "green").length;
```

How many equilateral triangles?

```
shapes.filter(
  (s) =>
    s.numSides === 3 &&
    s.sideDims[0] === s.sideDims[1] &&
    s.sideDims[1] === s.sideDims[2]
).length;

shapes
  .filter((s) => s.numSides === 3)
  .filter(
    (s) => s.sideDims[0] === s.sideDims[1] && s.sideDims[1] === s.sideDims[2]
  ).length;
```

Largest perimeter?

```
shapes
  .map((shp) => {
    let perimeter = 0;
    // Compute perimeter
    return perimeter;
  })
  .reduce((acc: number, curr: number) => {
    if (acc > curr) return acc;
    else return curr;
  });
```
